The Benefit of Positive-Negative Criteria-Based Assessment in Prediction of No Improvement after Nonsteroidal Anti-Inflammatory Drug Discontinuation in Patients with Rheumatoid Arthritis. Recently, there has been an emphasis on the use of such measures as the evaluator's global assessment and the disease activity score to predict the likelihood of clinical remission, or in other words, the likelihood of nonimprovement during treatment with nonsteroidal anti-inflammatory drugs (NSAIDs) in patients with rheumatoid arthritis (RA). The aim of this study was to investigate whether the benefit of positive and negative criteria assessment is equal when predicting non-improvement after discontinuation of NSAIDs. Data were collected from rheumatologists in Finland who were asked to assess RA patients before and after discontinuation of NSAIDs. At one center, 83 RA patients who discontinued NSAIDs were examined, and at another center, 59 RA patients who continued to take NSAIDs were examined. The results from the study showed that at both centers, the patients who were not expected to show improvement had significantly greater negative predictive values (NPVs) (p Wavelet-based image inpainting for tissue segmentation. Image inpainting is an important problem in image processing for restoring an image damaged in part or in whole. Many techniques have been proposed to solve this problem and can be classified into three main categories: global methods, patch-based methods, and patch-based with a shape prior. Among them, patch-based methods are easy to implement and have achieved good results; however, the efficiency of these methods may be low when dealing with a large image. We propose a novel wavelet-based inpainting technique for the segmentation of bioimages. The main idea of our method is to utilize the edge information of a small subregion of the image to compute a reconstruction of the missing
